ABSTRACT

A program has been written for the HP-97 (HP-67) minicomputer to solve the blast wave from a nuclear detonation. The program first determines standard-altitude parameters for the altitude of interest. Using these parameters as input, the program then calculates pressures, temperatures, densities, velocities, and Mach Numbers in front and behind the shock. Three subroutines allows the user to input (for any altitude) 82,000 ft) a specific overpressure across the shock, a specific gust velocity behind the blast wave, or a specific dynamic pressure behind the blast wave. Corresponding parameters for each input are calculated.

NUCLEAR BLAST PROGRAM

For Mini-Calculators

Introduction

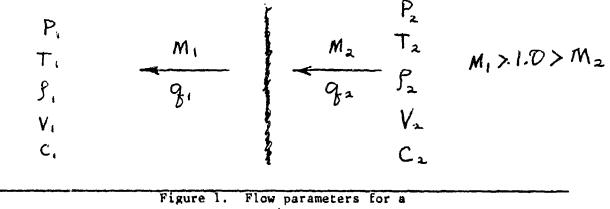

In the process of performing calculations of the values of the pressures, temperatures, velocities, densities, etc. behind weak shock waves at some distance from a nuclear detonation, it became obvious that hand calculation was tedious and interpolation from graphical results subject to e-ror. Therefore a simple program was developed for use on the HP-97 (or HP-57) mini calculator to perform these operations. This program is described in the following narrative.

Although this simple program is not intended to replace the more sophisticated computer codes available for such computation, it is a valuable tool for first cut analyses. It also has the distinct advantage of being highly portable, and serves as handy reference for use when the detailed data are not immediately available.

Discussion

At distances from any nuclear detonation of interest to the analyst working with airborne systems, the blast wave is relatively weak and amenable to solution via standard fluid mechanical equations. The first step in such a solution is the application of standard fluid dynamical equations used to solve the stationary shock. See Figure 1. The governing equations relating conditions in front of and behind the shock can be obtained from any text on supersonic flow. I used Shapiro*.

* A. H. Shapiro, The Dynamics and Thermodynamics of Compressible Fluid Flow. Ronald Press, N.Y. 1953

stationary shock wave

After solving the stationary shock problem, I then transformed the problem into a moving shock, or blast wave problem by allowing the shock to move with a speed such that its Mach number was equal to M₁. This system uses primed variables and is depicted in Figure 2.

$$P_{1}' = P_{1} \qquad q_{1}' = 0 \qquad \qquad P_{2}' = P_{2} \qquad T_{2}' = T_{2} \qquad S_{2}' = S_{2} \\ C_{2}' = C_{2} \qquad \qquad C_{2}' = C_{2} \\ M_{1}' = T_{1} \qquad M_{1}' = 0 \qquad \qquad M_{SHOCK} \qquad \qquad M_{SHOCK} \qquad \qquad M_{2}' = \frac{V_{2}}{C_{2}} = \frac{V_{1} - V_{2}}{C_{2}} = \frac{C_{1}}{C_{2}} M_{1} - M_{2} \\ g_{2}' = \frac{S}{T_{2}} \qquad F_{2}' M_{2}'^{2} = \frac{1}{T_{2}} \qquad S_{2}' V_{2}'^{2} \\ V_{1}' = 0 \qquad \qquad V_{1}' = 0 \\ C_{1}' = C_{1} \qquad Figure 2. Flow parameters for moving shock in terms of stationary shock solution \\ \end{array}$$

As depicted in Figure 2, the stationary shock solution provides all the data needed to solve the blast wave problem. The parameters of most interest to the nuclear survivability/vulnerability analyst are V_2 ' (the gust velocity), the overpressure, $(P_2' - P_1' = P_2 - P_1)$ and the dynamic pressure, q_2' .

The program incorporating the colution of the blast wave is listed in the Appendix B and detailed operating instructions are contained in Appendix A. The "guts" of the program is subroutine B, which solves the stationary shock then utilizes that solution to solve the blast wave (moving shock) for any selected altitude and overpressure. Subroutines C and D accept gust velocity and dynamic pressure inputs respectively and iterate back through the basic part of subroutine B until the calculated quantity is within the acceptable tolerance of the input.

Subroutine A is the cornerstone of the program. It contains analytical expressions describing the variation of the standard atmosphere with altitude as presented in Dommasch.* For the specified altitude these equations are solved, resulting in ratios of the values of the parameter of interest at altitude to the see level standard value. Multiplication of these ratios by the pertinent see level standard results in the desired value at altitude. These values are stored and also used in subsequent calculations. Note that because of program step limitations, the program was separated into two parts. Part 1 is pertinent for the troposphere ($h \leq 36,000$ feet) while part 2 is accurate in the stratosphere (36,000 contained the secondard with altitude.

CONCLUSION

The program presented herein should prove to be a valuable tool to analysts dealing with weak blast waves of any type, but should prove of particular interest to nuclear survivability/vulnerability analysts in government and industry.

*D. O. Dommasch, S.S. Sherby, and T.F. Connolly, <u>Airplane Aerodynamic</u>, Pitman Publishing Corp. N.Y. 1961.

Appendix A OPERATING INSTRUCTIONS NUCLEAR BLAST PROGRAM

I. Subroutine A, Calculation of Ambient Atmospheric Parameters.

Upon loading the program, the first step must be the utilization of Subroutine A to calculate the ambient static pressure and temperature at the altitude of interest. The other subroutines use these parameters, and will not function unless the calculations are made. Note: Load Part 1 if altitude of interest is 36,000 feet or less, load Part 2 if the altitude of interest is between 36,000 and 82,000 feet.

PRESS A - This step clears all registers and sets up the program. ENTER ALTITUDE - Altitude is in feet.

PRESS R/S - Calculation requires a few seconds. When the altitude is displayed, calculations are complete. Secondary registers contain results

of the calculations.

	SECONDARI REGISIERS										
0	1	2	3	4	5	6	7	8	9		
Ð T/r.	5) (P/Po)	(9/9c)	T °R	P (Fsia)	9 (finge/A3)	C (St/sec)	-	_	h (5======)		
-	(P/Po)	0	(°R)	P (Psia)	9 (siuzs/ft ³)			-	h (seet)		

$$**T = constant = 390 °R$$

To recall these parameters, press t, then PZS. Use RCL for register of interest. Prove to use of other subroutines either restore the original configuration (i, PZS) or restart program.

II. Subroutine B - Calculation of Gust Velocity (given an Overpressure).

This subroutine accepts an overpressure (in psi) and solves the blast wave. The gust velocity is displayed at the completion of the calculations. (Recall that Subroutine A must be exercised at least once prior to use of this subroutine. The results of the subroutine are pertinent <u>only</u> for the last altitude entered in Subroutine A.)

PRESS B Initializes subroutine

```
ENTER OVERPRESSURE in psi. Recall overpressure = P_2 = P_1.
```

PRESS R/S After calculations are complete, gust velocity is displayed.

At the point the user has several options. If the gust velocity corresponding to the selected overpressure for a different altitude is desired, press A, enter the new sltitude, press R/S, then exercise subroutine B again. If various overpressure/gust velocity pairs are desired for the selected altitude, it is not necessary to recalculate the atmospheric parameters, press B, then enter the overpressure. The corresponding gust is displayed.

III. Subroutine C. Calculation of Overpressure (given a gust velocity).

This subroutine accepts a gust velocity (in feet/second) and calculates the corresponding overpressure via iteration through the basic solution incorporated in subroutine B. This subroutine may be exercised immediately after the altitude computations, or the completion of any of the other subroutines.

8

PRESS C	Initializes subroutine
ENTER GUST VELOCITY	feet/second
PRESS R/S	Several iterations may be necessary for
	convergence. After the calculations are complete,
	the overpressure is displayed.

If other gust velocity/overpressure pairs are desired for the <u>same</u> altitude, simply repeat the above steps. If a new altitude is desired, subroutine A must be reaccomplished prior to initialization of subroutine C.

IV. Subroutine D. Calculation of the Overpressure and Gust Velocity (given a dynamic pressure).

This subroutine accepts a dynamic pressure in psi and calculates the corresponding overpressure and gust velocity via interation. This subroutine may be exercised immediately after the completion of subroutine A, or upon completion of any of the other subroutines.

PRESS D Initializes subroutine. ENTER DYNAMIC PRESSURE in psi. <u>NOTE</u>. A maximum of 3 places after the decimal will be tolerated --- otherwise program cycles endlessly.

PRESS R/S Several iterations may be required for convergence after calculations are complete, overpressure is displayed.
PRESS R/S Gust velocity is displayed.

V. Miscellaneous Notes

1. If the program cycles endlessly, or if an error is indicated in the display, press A twice to clear.

9

2. The exercise of autrophines B, P, and D results in much data being generated. In each case, only one (or two for D) parameters are displayed," but other shock wate solutions are stored and may be recalled, if they are needed. The register contents are depicted below. Variable lubels are from figures 1 and 2.
